Soft-Field Takeoff and Climb

Objective

To ensure the applicant learns the purpose of and can exhibit a clear understanding of the soft-field takeoff maneuver and how to perform the maneuver properly.

Purpose

Schedule

The soft field takeoff maneuver is used when departing from grass or other soft landing surfaces. It demonstrates how the airplane needs to be handled differently on these high-drag surfaces. Mastering this maneuver will help pilots become comfortable operating to and from grass strips.

Scriedule		Equipment
•	Ground Lesson: 15 minutes Initial Flight 1: 40 minutes - Introduction to Maneuver Flight 2: 50 minutes - Improve Proficiency (Dual) Solo Flight 3: 30 minutes - Improve Proficiency Pre-Checkride Flight 4: 20 minutes - Demonstrate Proficiency Debrief: 10 minutes (per flight)	 Airplane POH and Checklist Whiteboard / Markers (optional) Model Airplane (optional)
Student Actions		Instructor Actions
•	Ask any questions, receive study material for the next lesson. Watch linked video. Review listed references.	 Deliver the ground lesson (below). Demonstrate the maneuver in flight. Debrief after each flight.

Fauinment

Completion Standards

- Ground: Student can explain the purpose of the maneuver and how to execute it properly.
 - Can explain how the nose wheel is protected, ground effect, and Vx vs Vy.
- **Flight**: Student can perform the maneuver to the applicable ACS standards.
 - Performs a pre-takeoff checklist and configures the airplane correctly.
 - Holds weight off of the nose wheel during taxi and aligns with the runway centerline without stopping.
 - Lifts off at the lowest possible speed and accelerates in ground effect to Vx.
 - Climbs out at Vx until clear of obstacles, then accelerates to and climbs at Vy.
 - See expanded Completion Standards below.

Ground Lesson Outline

- What are Soft Field takeoffs?
 - Protecting the nose wheel
- Importance of Estimating Field Conditions
- Ground Effect
- Takeoff Performance
 - o Density Altitude
 - Calculating takeoff performance data
 - o Soft fields affect performance
- Runway Safety
- Safety considerations
 - Use of checklists
 - Visual traffic scanning awareness of obstacles and field condition
 - o Runway incursion avoidance
 - Be ready to abort!
- Maneuver Description step-by-step
 - Entry position, airspeed, etc.
- Expanded Completion Standards

Common Errors

- Improper runway incursion avoidance procedures.
- Improper use of controls during a soft-field takeoff.
- Improper lift-off procedures (climbing out of ground effect prematurely).
- Improper climb attitude, power setting, and airspeed (Vy or Vx).
- Improper use of checklist

Ground Lesson Content

• What are Soft Field takeoffs? Taking off from a grass or other soft-surface runway (soft field) has a few important differences from normal landings made on paved runways. Pilots may generally assume that paved runways are maintained in acceptable conditions, however soft fields have no such guarantees. Soft fields may be contaminated with water, mud, rocks, or covered in potholes or other hazards. Even fields which may from a distance appear quite dry can be unexpectedly muddy or wet.

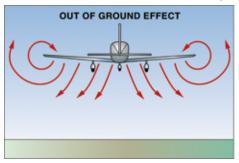

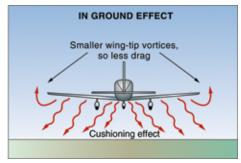

- Because most common training airplanes have *tricycle* landing gear, with heavy engines resting above small nose wheels, special care must be taken to prevent the nose wheel from sinking into the grass or mud and slowing the airplane excessively.
- Grass and other soft surfaces, such as dirt, provide a significant amount of increased drag or rolling resistance as compared to paved runway surfaces. Therefore, landing distances will be improved, however takeoff distances can be lengthened dramatically. Taxiing will also require considerably more power, and require careful attention to keeping weight off of the nosewheel!
- The best way to protect the nose wheel on soft-surface fields is to keep full back elevator pressure whenever in motion on the soft surface, avoiding wheel braking, and avoiding coming to a complete stop whenever possible.
- Importance of Estimating Field Conditions If the condition of a soft field is not already known, it is generally a good idea to inspect it closely to assess the field conditions. The surface should appear dry, the grass properly mowed, and free of potholes and rocks.

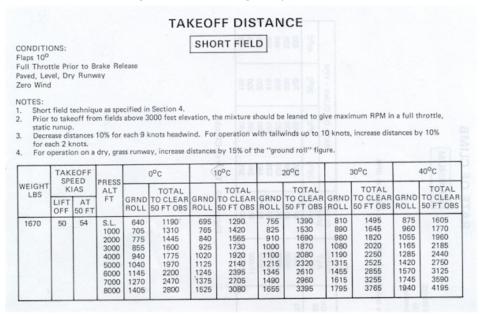

- Very early in the takeoff roll the nose wheel will come off the surface. Some back elevator pressure will
 need to be released to allow the airplane to accelerate some, but eventually the airplane will want to
 begin to lift off.
- **Ground Effect** As the airplane lifts off, and remains just above the ground, it is flying in *ground effect*. *Ground effect* is a phenomenon where the proximity of an airplane's wing to the ground interrupts the usual wing tip vortices and provides a cushioning effect.

- Flying in ground effect will allow the airplane to lift off at a lower than normal speed. It will also allow
 the airplane to continue to accelerate to an airspeed which will allow it to climb away from the ground
 safely.
 - On many soft surfaces, the rolling resistance is so great it may be impossible to accelerate to flying speed without getting into ground effect!
 - In these situations, it may be necessary to 'unstick' the airplane from the soft surface by briskly pulling back on the elevator to get airborne and into ground effect.
 - It is important to realize that if the airplane tries to climb out of ground effect before it accelerates to a normal climb airspeed (usually Vx), it may enter a stall or settle back to the surface!
- Ground effect only occurs within a very short distance above the surface. Generally, the effect is almost completely gone by 1 wingspan distance from the ground, and is strongest within ½ a wingspan from the ground.
- Takeoff Performance Determining exactly how much distance will be required for takeoff is crucial to
 ensure the chosen runway will be long enough to depart safely. An airplane's takeoff performance is
 highly dependent on several changing factors, such as weight, wind, and density altitude. Aircraft
 performance at heavier weights or higher altitudes is greatly reduced.

- Density altitude, which is a correction for atmospheric conditions, is the altitude that an airplane 'feels'.
- At higher altitudes or on hot days, the density of the air will be less and therefore the airplane will need to move more air to stay aloft. Because the airspeed indicator is also affected by density altitude, it will show the same values, however the true airspeed will be higher.
- The difference between field altitude and the density altitude can be significant!
 - See the related lesson on Density Altitude.
- The POH for every aircraft will contain performance charts that detail how many feet of takeoff distance is required for various weights, winds, and weather conditions. It also prescribes an airplane configuration that should be used.
 - To use the performance charts, first find the pressure altitude, by setting the altimeter to 29.92" or using the conversion. Then, find the cell in the table that matches the airplane gross weight with the pressure altitude and the current temperature. Make sure to read the notes, in case distances need to be adjusted for wind or other conditions! Remember that a soft field will always require more takeoff distance than a paved runway, so takeoff performance figures need to be adjusted.
 - It is best to add a 'safety factor' to the performance figures obtained from the POH performance charts. Generally, it is a good idea to overestimate the pressure altitude and temperature for a worst case scenario, and add 20-30% to account for the possibility of imperfect technique.
 - Don't forget to consider wind! A tailwind dramatically increases takeoff and landing distances. Likewise, a strong headwind can greatly improve performance.

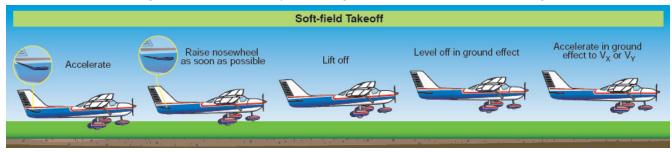

- Runway Safety All takeoffs generally start with the airplane crossing over a *hold short* line, which is the line that indicates where the runway area begins. Hold short lines should be taken very seriously!
 - Before crossing a hold short line:
 - At a towered airport, the pilot must have received a taxi, runway crossing, or takeoff clearance for the runway they are about to enter.
 - At a non-towered airport, the pilot has communicated their intentions over the radio (Common Traffic Advisory Frequency--CTAF), and has visually verified that there is no traffic on final approach for the runway, or on the runway itself, which would conflict.

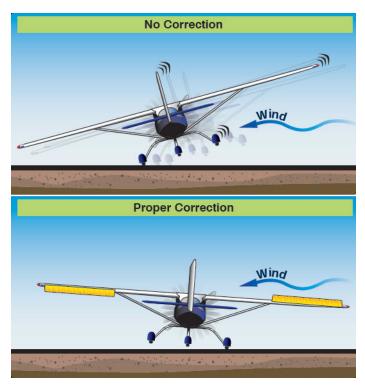

Safety Considerations

- As with any takeoff, the use of checklists is important. Before entering the runway area, the before takeoff checklist must be completed.
- Soft-field takeoffs require special caution to be exercised for adequate field surface conditions and watching for obstacles on or near the field! Powerlines, tall trees, or other obstacles may be quite close to the runway environment! These obstacles may be difficult to see in a nose-high attitude after takeoff, so a thorough takeoff briefing which highlights these hazards should be conducted before every takeoff.
- It is crucial to not become so focused on performing the maneuver that an unsafe situation is created. Maintain situational awareness, make appropriate radio calls, and ensure that takeoff clearance is obtained before entering any runways, if at a controlled field. Vigilance must be maintained to avoid taxiing onto any intersecting runways beyond other hold short lines. At uncontrolled fields, clearly communicate your taxi and takeoff intentions on the radio. Remember that uncontrolled fields often have no-radio (NORDO) pattern traffic, so always visually verify the runway and final approach path is clear!
- o If the airplane is not accelerating as expected and the takeoff is in doubt, **abort!** This is especially important on soft fields, where an unexpectedly wet or soft runway surface may produce enough rolling resistance that takeoff is impossible!

Maneuver Description

- Selecting a Suitable Surface Select a runway or suitable soft field surface that will allow takeoff into the wind, or with a manageable crosswind. When using an actual soft-field, it is best to first inspect the field to verify that it is free from large potholes, ruts, mud, or other debris that may damage the airplane.
- **Checklists** Pilots must perform a before-takeoff checklist before beginning the maneuver, and thoroughly brief any hazards that may be present on departure.
- **Taxiing** Taxi with full elevator backpressure to keep weight off of the nose wheel and avoid use of brakes or coming to a complete stop.
- **Before Takeoff** Configure the airplane for soft-field takeoff (per the POH), usually requiring flaps.
- **Entering the Runway** Taxi into the runway and smoothly line up with the centerline without stopping. Apply full power while holding elevator backpressure.
- Takeoff Roll and Liftoff The nose wheel should come up very early in the takeoff roll. Gently release
 elevator pressure to allow the airplane to accelerate while keeping the nose wheel off the ground.
 Positive aircraft control must be maintained at all times! Apply and hold proper crosswind
 corrections to avoid sidewards drifting. Allow the airplane to lift off and quickly push forward on
 the elevator to enter ground effect and fly level in ground effect while accelerating.

- Climbout Once the airplane has accelerated to Vx in ground effect, climb at Vx until any obstacles
 are cleared. After all obstacles are cleared, reduce pitch, retract flaps, and accelerate to Vy. Make
 sure to fly coordinated. More right rudder!
- This is a visual maneuver! Eyes should remain outside the cockpit as much as possible to scan for traffic and ensure proper tracking of the centerline. *Monitoring for other traffic is especially critical when performing this maneuver at uncontrolled airfields.*

Expanded Completion Standards

- The pilot can explain the purpose of the soft-field takeoff maneuver and how the various factors affect the performance of the maneuver.
- The pilot can perform the maneuver to the following standards:
 - Pilot configures the airplane properly for takeoff, performs a pre-takeoff checklist, ensures that takeoff clearance is obtained (at a towered airport) or that the runway and final approach path is clear (at a non-towered airport), and makes the appropriate radio calls.
 - Pilot maintains full elevator backpressure while taxiing, avoiding coming to complete stops, and smoothly taxis onto the runway area and aligns with the centerline.
 - o Pilot raises the nosewheel on takeoff roll, lifts off early, and remains in ground effect.
 - o Pilot accelerates to Vx in ground effect, and climbs out at Vx until clear of obstacles.
 - After clear of obstacles, pilot properly reconfigures airplane and accelerates to Vy.
 - Pilot divides attention between accurate, coordinated airplane control and outside visual references.
